

# Reference Frames, Transformations and GIS

Franco S. Sobrero  
The Ohio State University  
USA

# Terrestrial Reference System

In principle a TRS should be invariant with time

example: Geocentric ITRS

# FIG/IGM-Chile Technical Seminar

## Reference Frames in Practice

## International Terrestrial Reference Frame

Altamimi et al., 2015

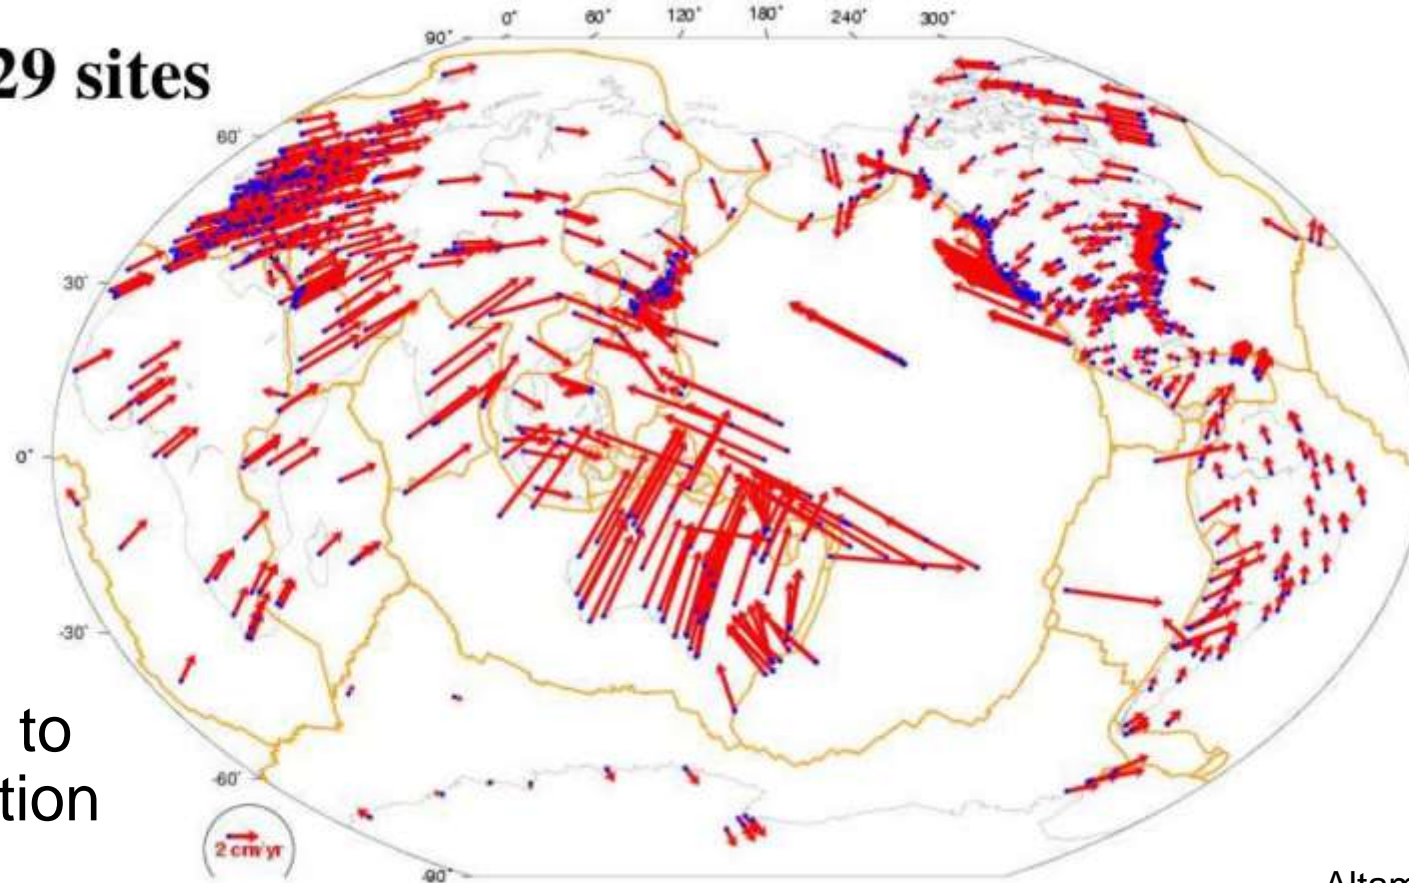

# FIG/IGM-Chile Technical Seminar

## Reference Frames in Practice

ITRF Kinematics – NNR site velocities (the angular momentum of all tectonic plates sums zero)

829 sites

Velocities are predominantly due to secular tectonic motion and GIA

Altamimi et al., 2015

# FIG/IGM-Chile Technical Seminar

## Reference Frames in Practice

## Regional Reference Frames

Plate fixed

e.g. European RF (ETRF) – velocities minimised for most of Eurasian plate  
(figure: EUREF, 2018)

NNR (No-Net-Rotation)

e.g. Asia-Pacific RF (APREF) – no dominant plate within frame coverage  
so NNR model is used (figure: Hu, 2014)

# FIG/IGM-Chile Technical Seminar

## Reference Frames in Practice

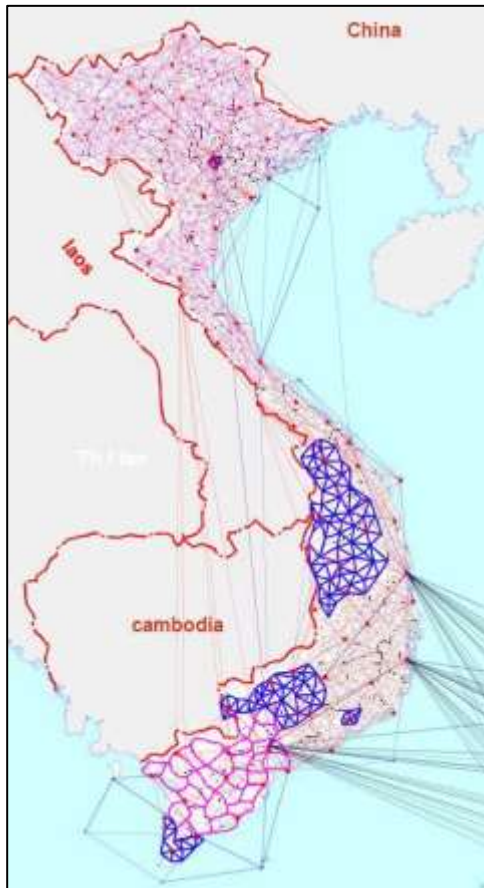

## National & Local Reference Frames

Characteristics:

Now usually a fixed epoch of ITRF using GNSS (recent geocentric frames) e.g. VN2000 for mainland Vietnam (figure: Vietnam Dept. of Surveying Mapping, 2016)

or astronomical determination of frame origin (pre space geodetic era)  
(frame often not geocentric)

e.g. Australian Geodetic Datum 1966 (AGD66)

(figure: Paul Wise, 2016)

## Static and time-dependent frames

Static (time-invariant) – no displacement is assumed

Kinematic (time dependent)

- includes all displacements wrt. ITRS  
(e.g., tectonic motion, glacial isostatic adjustment, coseismic deformation)

Semi-kinematic (time dependent)

- secular tectonic motion is modelled out
- coseismic displacement models applied after earthquakes

# FIG/IGM-Chile Technical Seminar

## Reference Frames in Practice

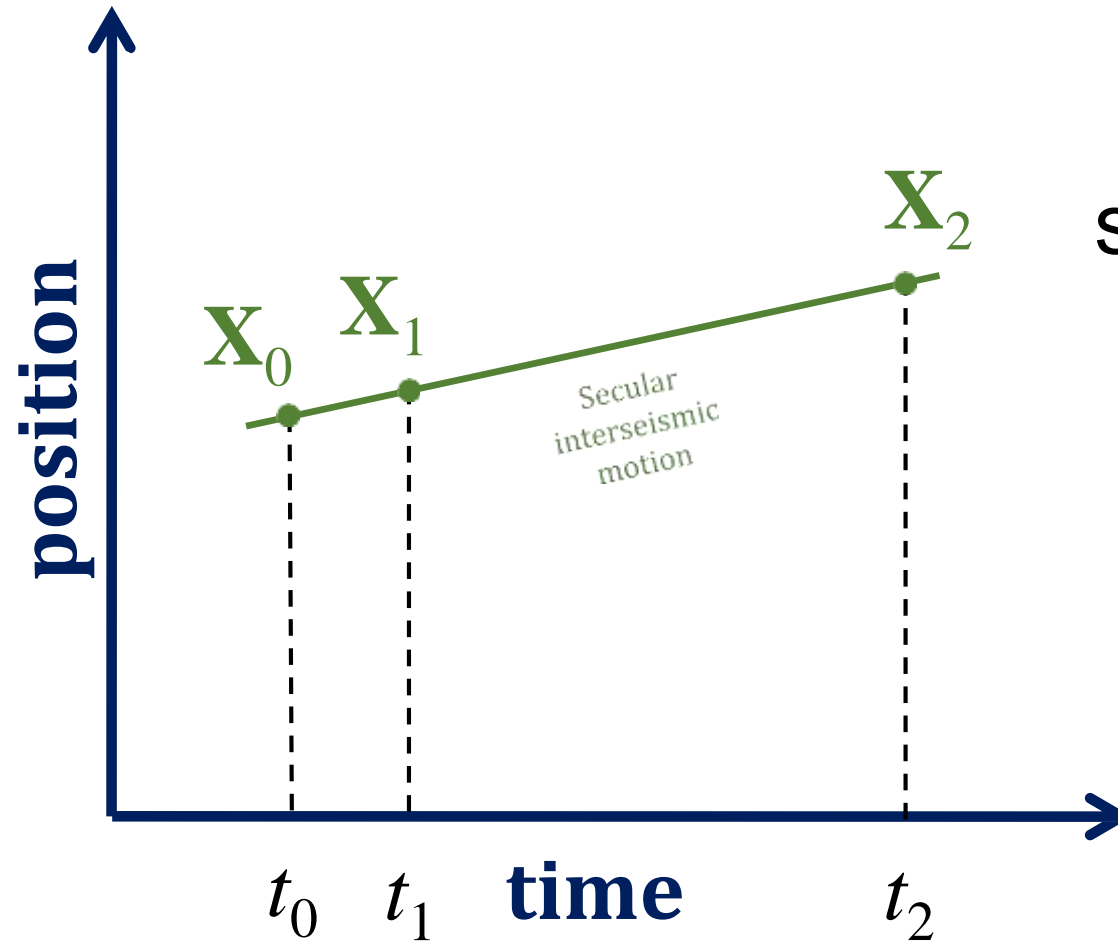

### Static reference frame

position does not change with time  
(except perhaps for readjustments)

# FIG/IGM-Chile Technical Seminar

## Reference Frames in Practice

Kinematic frame –  
stable plate regions

position changes  
slowly ( $< 8 \text{ cm yr}^{-1}$ )  
due to secular plate  
motion and GIA  
(interseismic motion)

# FIG/IGM-Chile Technical Seminar

## Reference Frames in Practice

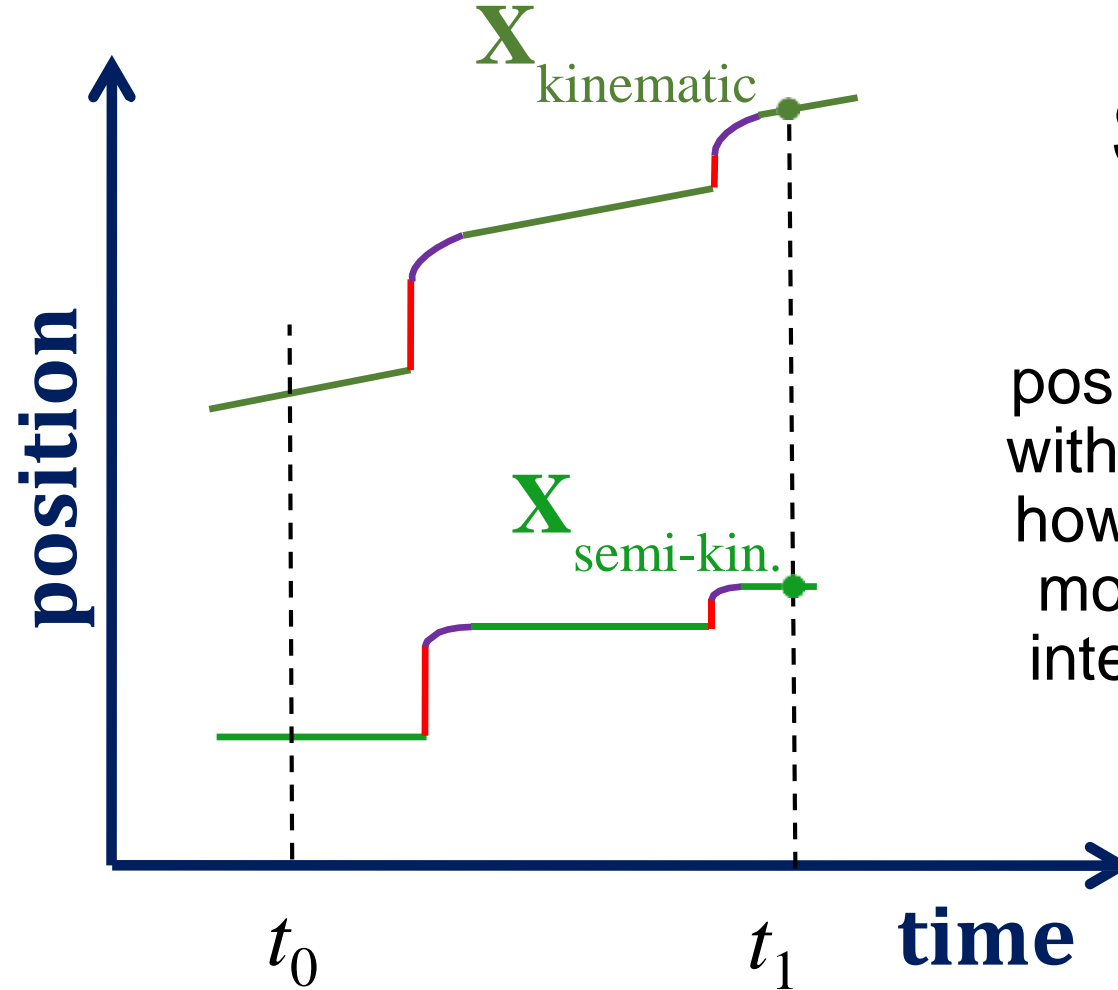

Kinematic frame –  
plate boundary  
zones

position changes  
episodically with coseismic  
and postseismic  
displacements resulting from  
earthquakes

# FIG/IGM-Chile Technical Seminar

## Reference Frames in Practice

## Semi-kinematic frame

position changes episodically with coseismic displacements however secular interseismic motion is modelled out until interseismic strain threshold is reached

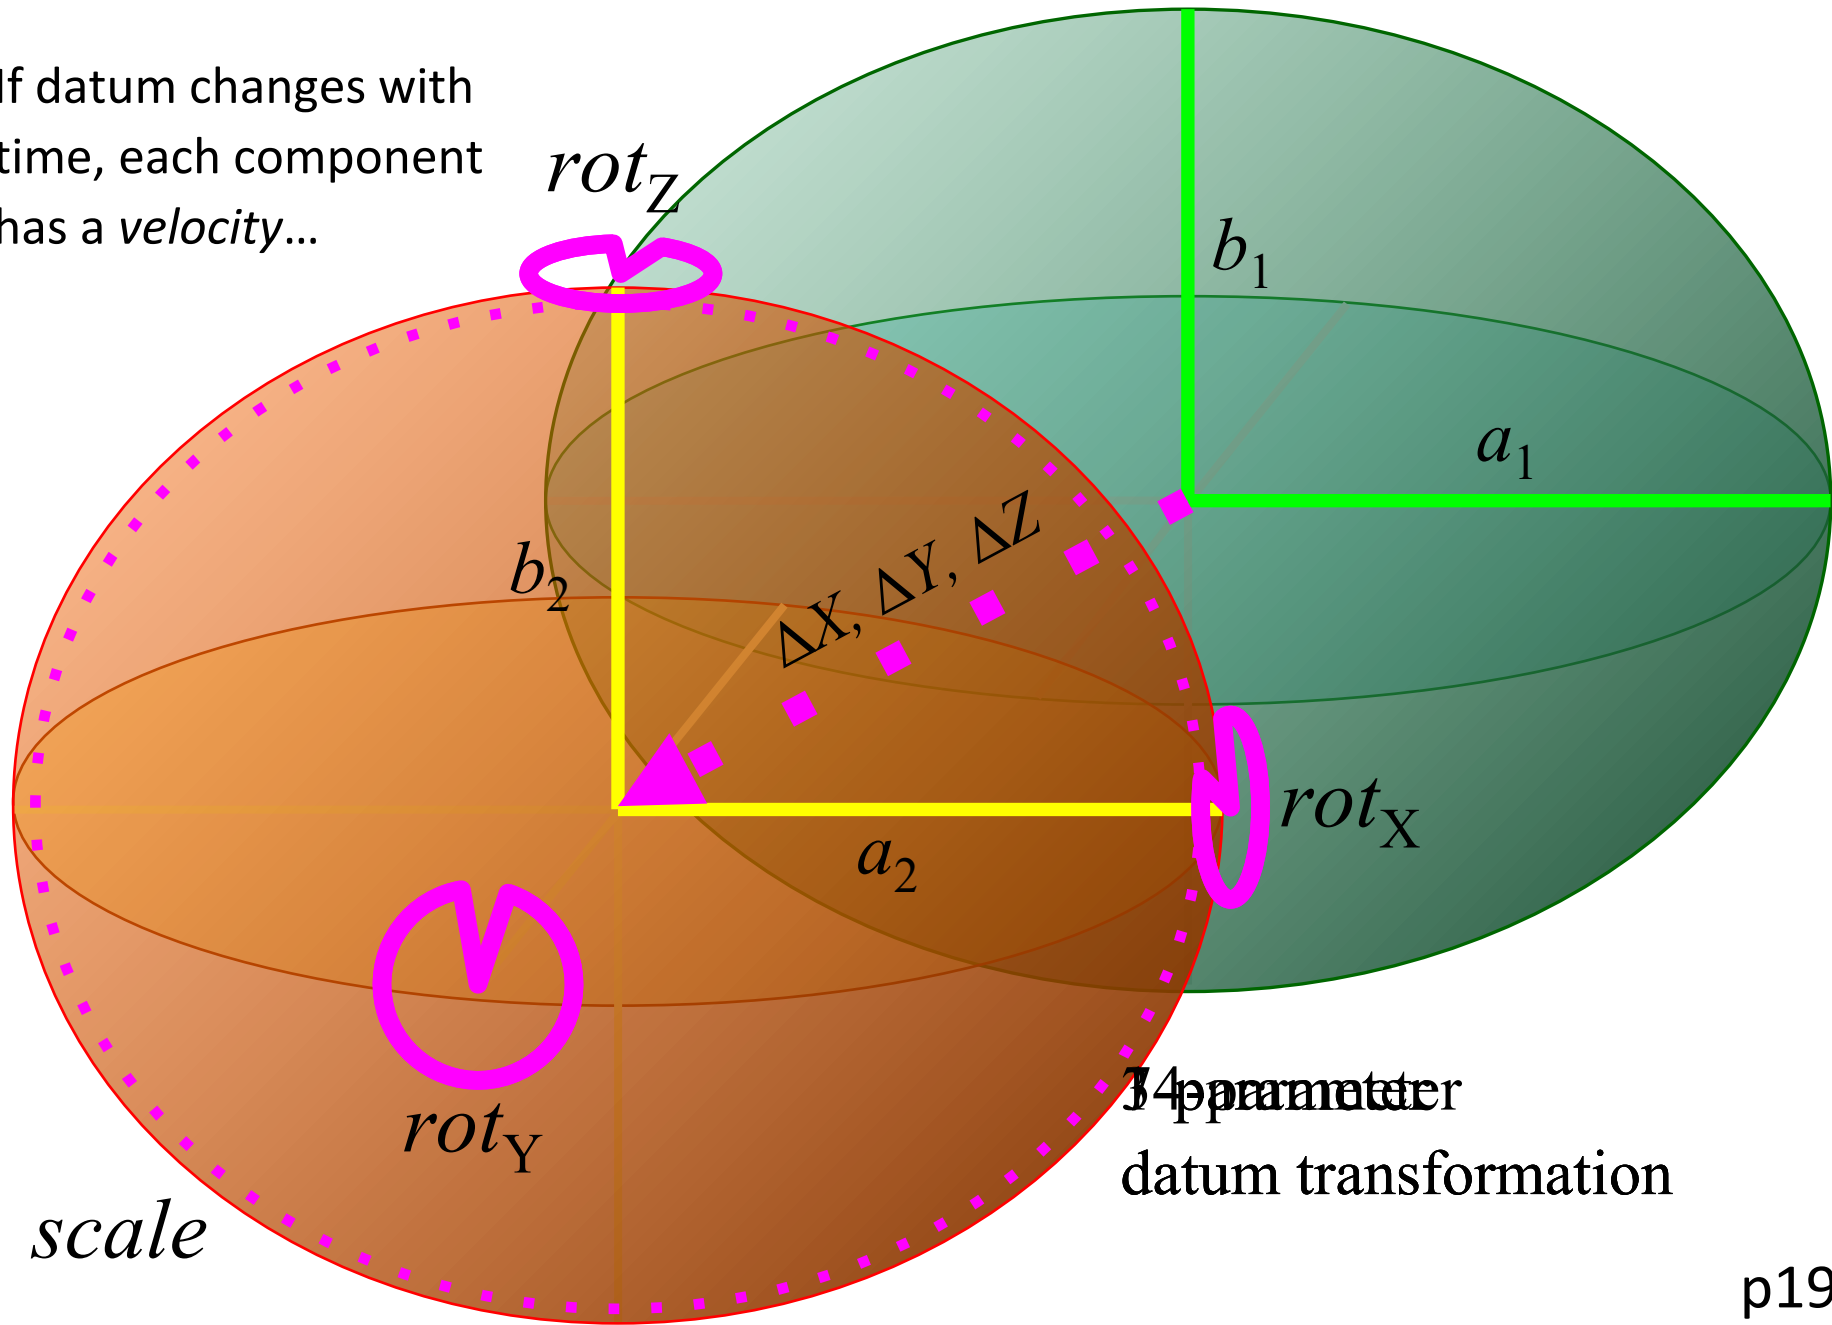

## Interframe transformations

	Static frame	time-dependent frame
Conformal Parametric	3 parameter 7 parameter	14 parameter (7 parameters at reference epoch + rates)
Grid model	displacement grid distortion grid	interseismic velocity model + coseismic displacement grid + postseismic decay term grid

# Geometric datum transformations

If datum changes with time, each component has a *velocity*...

# Datum transformations

- **Typical geodetic datum transformations**
  - **3-parameter:** 3-dimensional translation of origin as  $\Delta X$ ,  $\Delta Y$ ,  $\Delta Z$  (*just like a GPS vector*)
  - **7-parameter:** 3 translations *plus* 3 rotations (one about each of the axes) *plus* a scale
  - **14-parameter:** A 7-parameter where each parameter changes with time (each has a *velocity*)
  - Transformations that also model distortion and tectonic motion, such as the NGS programs NCCAT and HTDP
- **Vertical datum transformations**
  - Can be simple shift or complex operations that model distortion, gravity, and tides, such as NGS programs NCCAT and VDatum

# Plate Motion Model

$$\begin{aligned} \Omega_x &= \cos(\Phi) \cos(\Lambda) \omega \\ \Omega_y &= \cos(\Phi) \sin(\Lambda) \omega \\ \Omega_z &= \sin(\Phi) \omega \end{aligned}$$

Plate	Euler pole of rotation			Equivalent Cartesian angular velocity		
	$\Phi$ (°)	$\Lambda$ (°)	$\omega$ (° Ma <sup>-1</sup> )	$\Omega_x$ (Rad Ma <sup>-1</sup> )	$\Omega_y$ (Rad Ma <sup>-1</sup> )	$\Omega_z$ (Rad Ma <sup>-1</sup> )
Antarctic	58.8	-127.4	0.219	-0.001202	-0.001571	0.003272
Arabian	51.2	-6.7	0.515	0.005595	-0.000659	0.007001
Australian	32.4	38.1	0.631	0.007321	0.005730	0.005890
Eurasian	55.1	-99.1	0.261	-0.000412	-0.002574	0.003733
Indian	51.6	-0.2	0.516	0.005595	-0.000024	0.007049
Nazca	45.8	-102.2	0.629	-0.001614	-0.007486	0.007869
North American	-5.2	-88.0	0.194	0.000116	-0.003365	-0.000305
Nubian	49.7	-80.8	0.267	0.000480	-0.002977	0.003554
Pacific	-62.6	111.3	0.679	-0.001983	0.005076	-0.010516
South American	-19.1	-131.9	0.119	-0.001309	-0.001459	-0.000679
Somalian	47.7	-98.7	0.332	-0.000587	-0.003849	0.004286

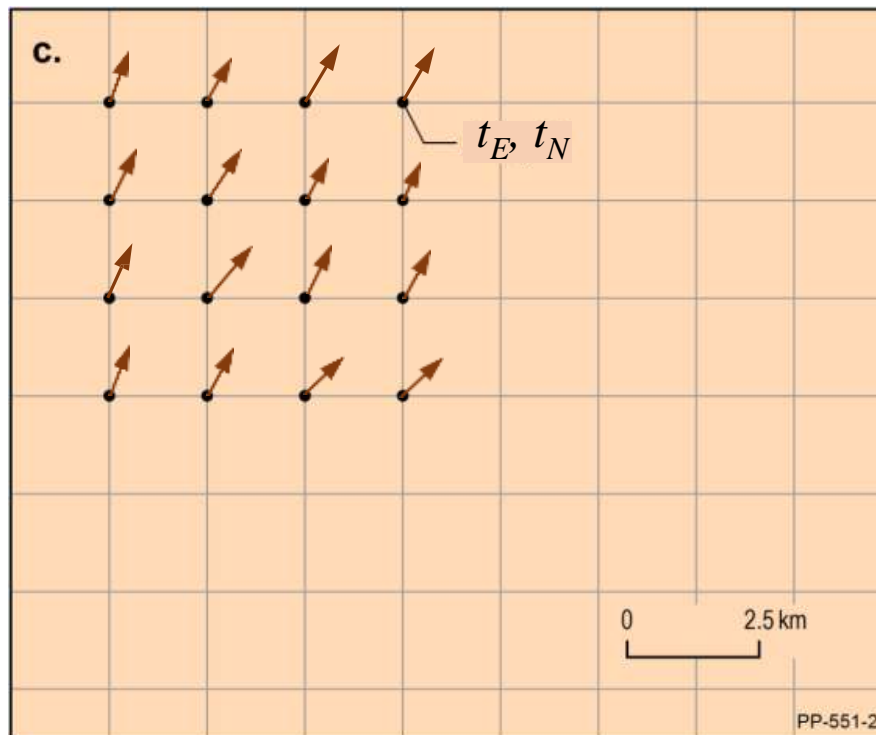

ITRF2014 Plate Motion Model (from Altamimi *et al.*, 2017)

Euler pole can be estimated by LS inversion of interseismic site velocities within a stable plate

Rotation rates can be used in a 14-parameter model with zeroes for other parameters (now used for GDA2020 to ITRF2014 transformations)

# Displacement and Distortion Grids

adapted from GDA2020 Technical Manual, ICSM, 2018

$$\begin{bmatrix} E \\ N \end{bmatrix} = \begin{bmatrix} E \\ N \end{bmatrix} + \begin{bmatrix} t \\ t \end{bmatrix}$$

Topocentric shifts estimated by bilinear interpolation of grid model (e.g., in NTV2 format)

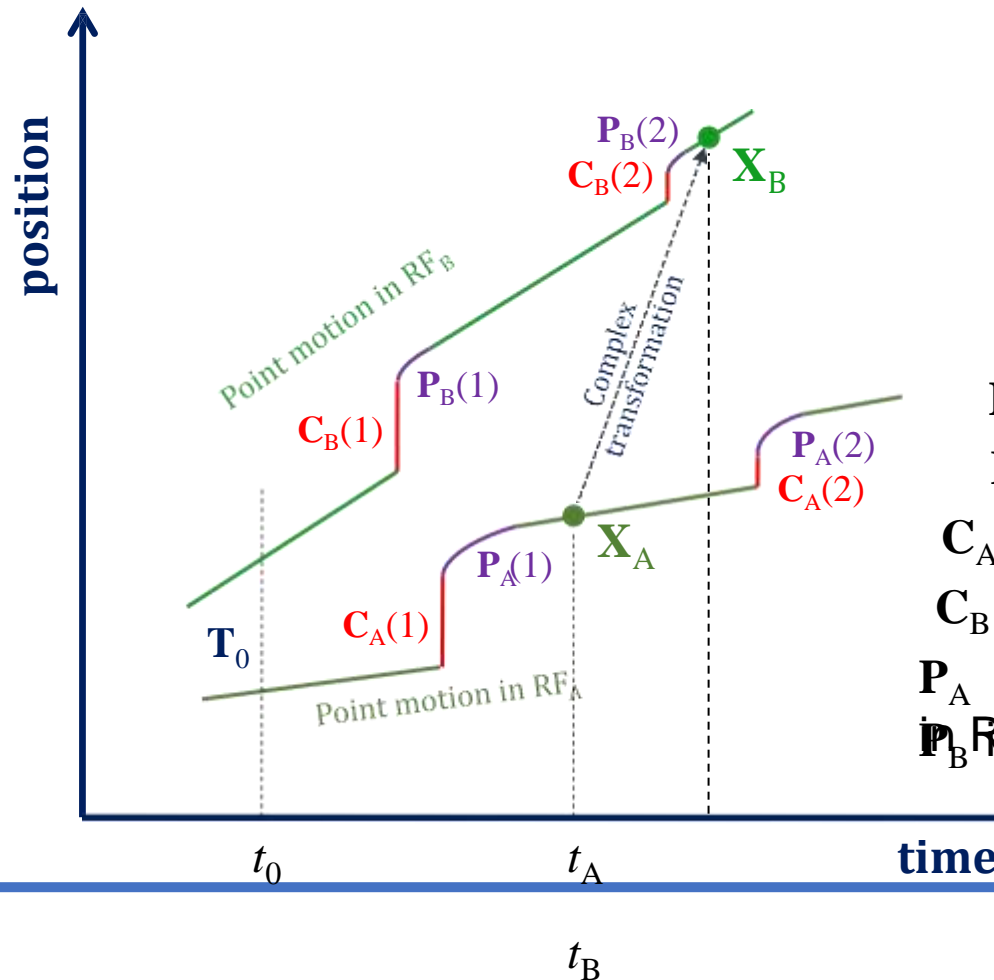

Ideal for heterogeneous RF transformations and handling local distortions

# FIG/IGM-Chile Technical Seminar

## Reference Frames in Practice

### Complex time-dependent transformations

$$\mathbf{X}_B = \mathbf{X}_A - \Delta\mathbf{X}_A + \mathbf{T}_0 + \Delta\mathbf{X}_B$$

where

$$\Delta\mathbf{X}_A = \mathbf{D}_A + \sum_{t_0 \geq \mathbf{C} > t_A}^n \mathbf{C}_A + \sum_{t_0 \geq \mathbf{P} > t_A}^n \mathbf{P}_A$$

$$\Delta\mathbf{X}_B = \mathbf{D}_B + \sum_{t_0 \geq \mathbf{C} > t_B}^n \mathbf{C}_B + \sum_{t_0 \geq \mathbf{P} > t_B}^n \mathbf{P}_B$$

$\mathbf{D}_A$  is secular displacement in  $\text{RF}_A$

$\mathbf{D}_B$  is secular displacement in  $\text{RF}_B$

$\mathbf{C}_A$  is coseismic displacement in  $\text{RF}_A$

$\mathbf{C}_B$  is coseismic displacement in  $\text{RF}_B$

$\mathbf{P}_A$  is postseismic displacement in  $\text{RF}_A$

$\mathbf{P}_B$  is postseismic displacement in  $\text{RF}_B$

$\mathbf{T}_0$  is interframe translation

# Topocentric frame

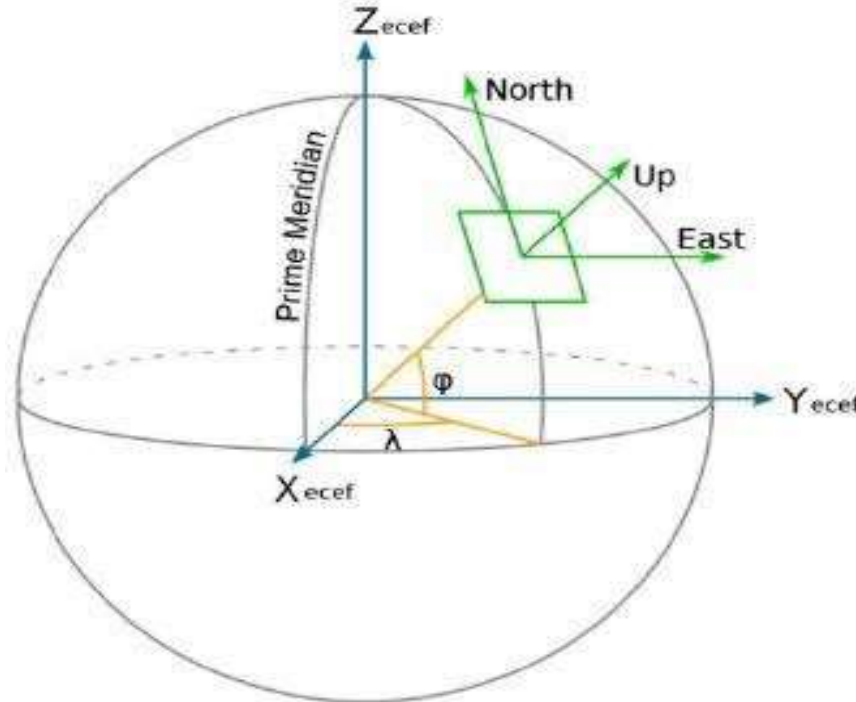

Image: Haasdyk and Janssen, 2011

A topocentric projection canvas is useful for complex transformation computations involving displacement grids

Converting geocentric translation to topocentric (rate or shift)

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = \begin{bmatrix} \cos\lambda \cos\phi & \sin\lambda \cos\phi & \sin\phi \\ -\sin\lambda & \cos\lambda & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} U \\ V \\ W \end{bmatrix}$$

Converting topocentric translation to geocentric (rate or shift)

$$\begin{bmatrix} U \\ V \\ W \end{bmatrix} = \begin{bmatrix} \cos\lambda \cos\phi & \sin\lambda \cos\phi & \sin\phi \\ -\sin\lambda & \cos\lambda & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \end{bmatrix}$$

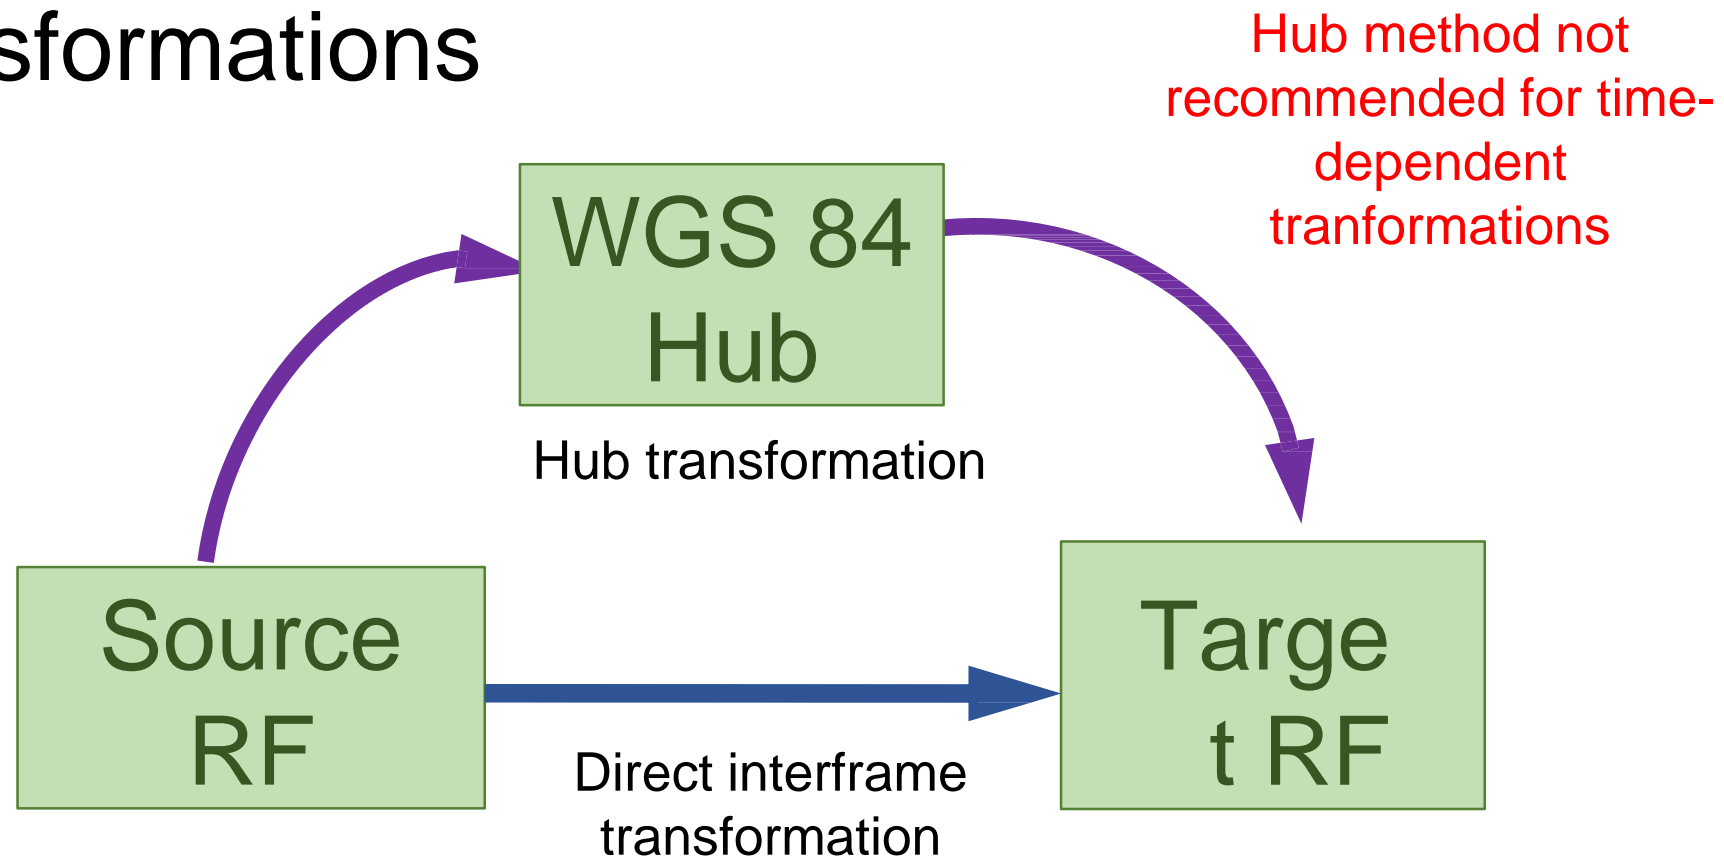

## GIS transformations

- All these transformations are used while working with GIS
- The main consideration is the alignment of precise data, defined in different RFs and **projections**.
- Geodetic Registries (EPSG and ISO Geodetic Registry) standardize definitions and transformation workflows for use in GIS, however there are still limitations with complex time-dependent RF.
- e.g. No standard for coseismic and postseismic displacement grids and no standardised epoch of WGS 84 when used as a hub transformation.
- Direct interframe transformations are the preferred option.

## GIS transformations
